INTEGRATED DEVELOPMENTAL SCHOOL

MIOW LMS Website audit

UI, UX, accessibility sample and performance inspection

Reviewed 7 October 2026 | Asia/Singapore

https://miow-lms.ter-ids.online/

6/10 overall

Consistent desktop foundation. Mobile login, dialog focus, and attendance navigation need priority fixes.

Report contents

Full written audit, prioritized findings, recommended fixes, scope and measurement limitations, and all nine original screenshots placed within the relevant findings.

Performance status: unmeasured. Chrome console and DOM inspection were available; Lighthouse and performance tracing were not. Reviewer ratings are subjective, not automated scores.

Read each finding alongside its screenshot evidence. Images retain their original resolution for closer inspection at higher zoom.

Verdict

MIOW has a recognizable visual identity and a usable desktop foundation. The supplied administrator login works, navigation is generally easy to understand, and search feedback is useful. The most consequential issues are mobile login overflow, keyboard focus escaping the student dialog, and the attendance page using teacher navigation inside an admin route. These should be addressed before polishing animation or decorative effects.

Subjective reviewer scores, based on the inspected admin experience:

Area	Score	Reason
Desktop visual design	7/10	Consistent brand, spacing, cards, and emphasis; small muted text and excessive empty space weaken readability and utility.
Task usability	5.5/10	Clear core sections and search; attendance destination and login recovery need work.
Mobile experience	4/10	Dashboard cards reflow, but login overflows and horizontal navigation hides destinations.
Accessibility sample	5/10	Inputs and icon actions have accessible names, but the tested dialog does not contain keyboard focus and mode selection is not exposed semantically.
Overall inspected experience	6/10	Promising foundation with several concrete usability defects.
Runtime performance	Unscored	Lighthouse, tracing, network timing, and Core Web Vitals measurements were unavailable through this Chrome connection.

These are editorial ratings, not automated Lighthouse scores or a complete accessibility conformance assessment.

Scope and method

Used the user's Chrome browser through the Chrome skill. An existing admin session was present at first; signed out and then successfully authenticated with the supplied account using the PIN form and Enter. Inspected the dashboard, Students, Teachers, Courses and a course detail, Announcements, Settings, Attendance, and both login modes. Opened the Add student dialog without submitting it and tested keyboard focus. Tested search with a no-match query. Inspected mobile login, dashboard, and settings. No school records, enrollments, announcements, grades, or configuration were changed. Signed out at completion and restored the normal viewport.

Desktop screenshots were approximately 1920 pixels wide. The mobile viewport override was requested at 390 × 844; the page reported a usable document width of 375 CSS pixels. Measurements below use the actual DOM width rather than assuming the requested width.

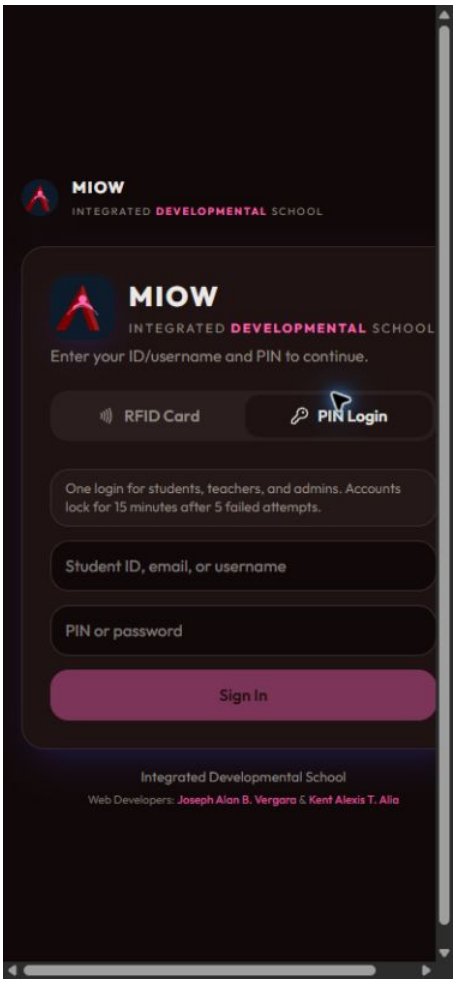

Chrome's available developer inspection included console warnings/errors, DOM structure, field semantics, and layout dimensions. It did not expose Lighthouse, the Network panel, a Performance recording, CPU/network throttling, or the page's Performance API. No LCP, INP, CLS, TTFB, payload size, or Lighthouse score is claimed.

Prioritized findings

1. High: mobile login overflows horizontally

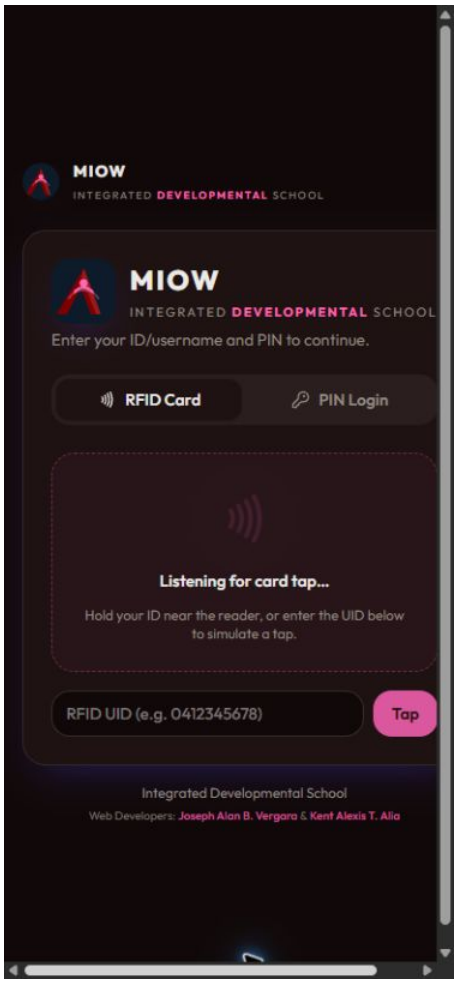

Both RFID and PIN login showed a document scroll width of **417 CSS pixels** against a **375 CSS pixel** client width: **42 pixels of horizontal overflow**. The brand text and right side of the login card are clipped; a horizontal scrollbar appears at the bottom.

Evidence 02 - Mobile PIN login

The card extends beyond the usable viewport; content is clipped on the right.

Evidence 03 - Mobile RFID login

RFID mode shows the same horizontal overflow as PIN mode.

Impact: the entry point feels broken on a common phone width, before a user reaches the otherwise responsive dashboard.

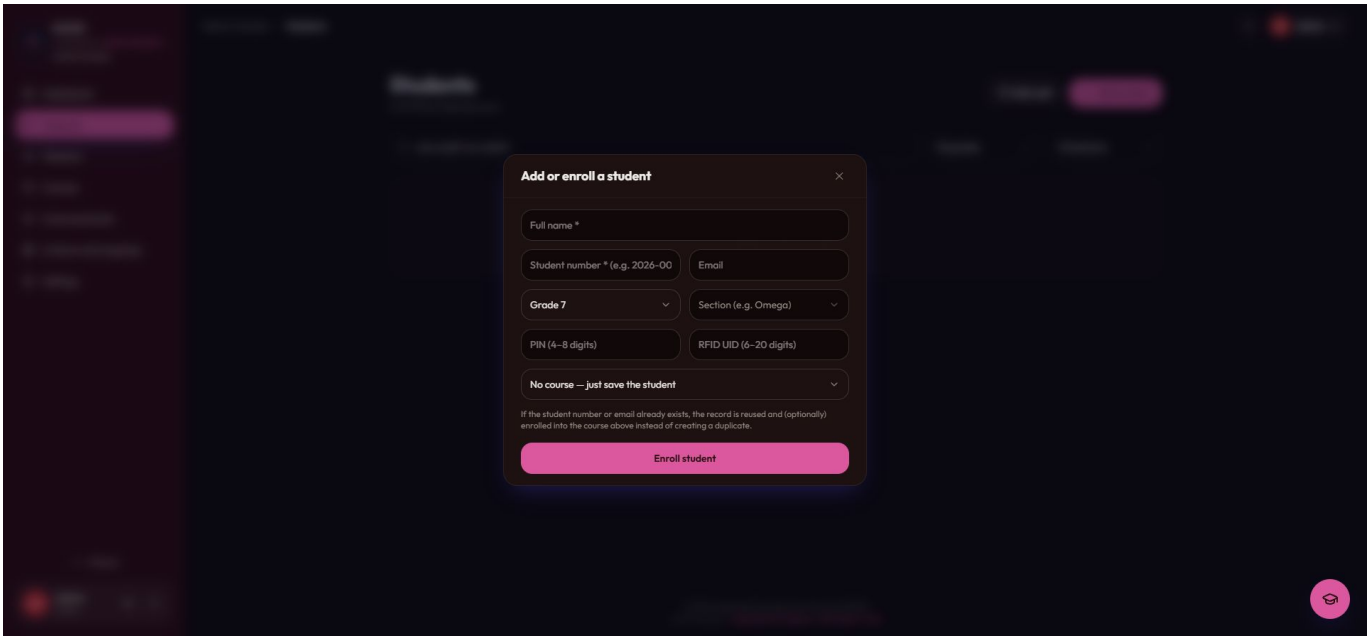

Fix: let the card shrink to the available width, apply **min-width: 0** where needed in flex/grid children, constrain decorative elements, and allow the long wordmark to wrap or use the compact brand. Correct the width source rather than only hiding overflow. Verify at 320, 360, 375, 390, and 414 CSS pixels.

Evidence: PIN login on mobile (Evidence 02), RFID login on mobile (Evidence 03).

2. High: Add student dialog does not contain keyboard focus

Opening Add student left **document.activeElement** on the underlying Add student button. Pressing Tab moved focus to the background Search students input. The open element with **role="dialog"** did not contain that focused input. Escape subsequently dismissed the dialog.

Evidence 06 - Add or enroll a student

Dialog layout. The focus defect was established by keyboard and DOM checks, not this image alone.

Impact: keyboard users can continue interacting with the obscured roster instead of entering the form, and screen-reader navigation can lose the modal context.

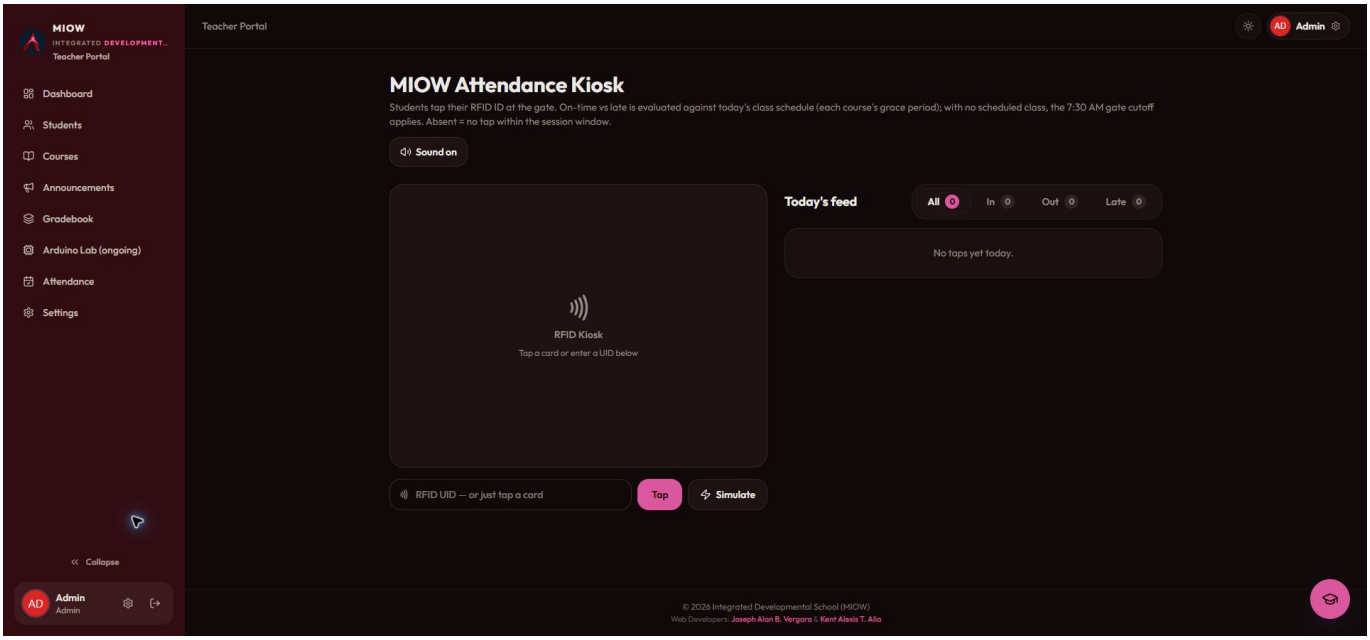

Fix: move focus into the dialog when it opens, trap Tab and Shift+Tab, make the background inert, expose the modal state and title, and restore focus to the trigger when closed. Keep the working Escape dismissal.

Evidence: Student form (Evidence 06). The focus finding comes from DOM inspection and keyboard interaction, not the screenshot alone.

3. High: admin Attendance switches the navigation to teacher routes

From the admin dashboard, the Attendance quick action is described as **View logs & reports**. It opens **/dashboard/admin/attendance**, but the page identifies its shell as **Teacher Portal** and its navigation links point to **/dashboard/teacher/...**. Its main content is an **Attendance Kiosk**, rather than an obvious historical reporting interface.

Evidence 08 - Admin attendance with teacher navigation

The admin attendance route displays Teacher Portal and a kiosk interface.

Impact: the user loses their admin navigation context and the destination does not clearly match the promised task.

Fix: render the admin navigation shell for the admin route; provide a clearly labeled kiosk action and a separate logs/reporting view if both workflows are supported. This observed routing mismatch is not proof of an authorization bypass.

Evidence: Attendance role mismatch (Evidence 08).

4. Medium: roster rendering creates a performance scaling risk

The unfiltered roster displayed **215 learners**. DOM inspection found **4,641 elements** and **124 image elements**, with **zero** images whose native **loading** property was **lazy**. No visible pagination controls were found, and the accessibility snapshot included the full roster.

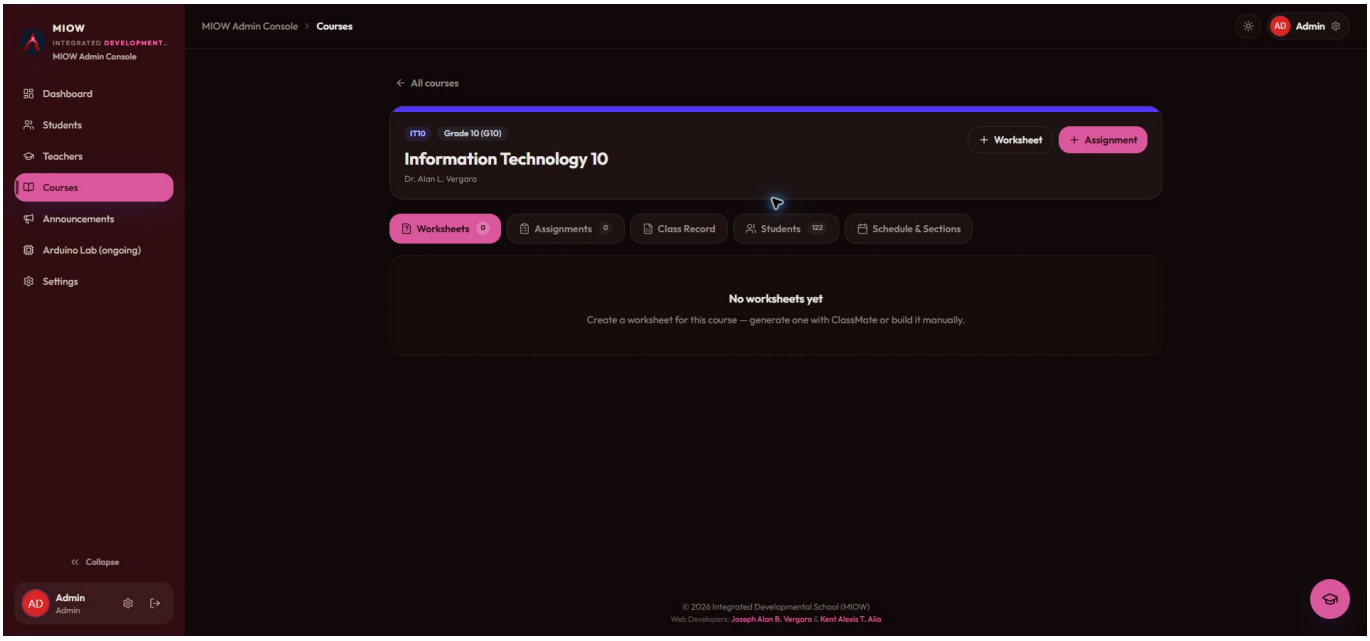

Impact: rendering the full roster and its avatars increases work as the school grows, especially on phones. Image element count does not equal measured network requests, and the absence of native lazy loading does not rule out another loading mechanism.

Fix: start with pagination of 25-50 learners and lazy loading of offscreen avatars. Ensure avatars have explicit dimensions and suitably small source images. If fast browsing of very large rosters is needed, consider virtualization after profiling. Retain useful search and filter feedback.

5. Medium: loading is temporarily presented as real zero data

On the first Courses view, cards showed **0 students enrolled**. Opening Information Technology 10 showed **Students 122**; returning to the list showed the actual values, including **122** for that course. The first zero values were therefore temporary loading values, not a lasting count mismatch.

Evidence 07 - Course detail

Information Technology 10 displays 122 students after enrollment data loads.

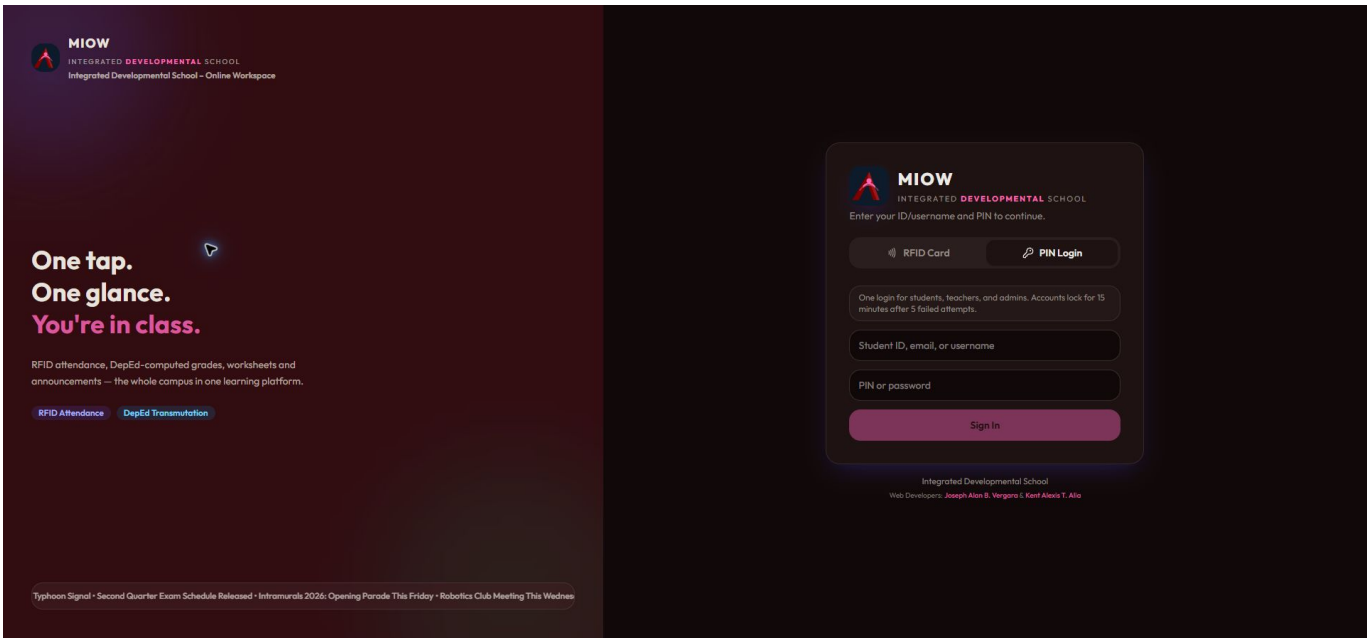

Teacher and Settings routes also initially exposed the navigation shell before their content appeared. The dashboard uses skeleton cards, which is a better pattern.

Fix: use a skeleton or an explicit loading placeholder until enrollment counts are available. Reserve **0** for a confirmed empty course. Keep route titles and loading feedback visible while content arrives.

6. Medium: login recovery and credential guidance are incomplete

The PIN mode accepts the provided administrator credentials and supports submitting with Enter. It masks the credential and has correct **username** / **current-password** autocomplete attributes. However, no visible recovery or help action was present, and the form relies on placeholder text for visible field identification. Fields do have accessible names through **aria-label**.

Evidence 01 - Desktop PIN login

Baseline login layout with PIN mode selected.

RFID is the default mode even in the tested mobile viewport. The default screen asks the user to hold an ID near a reader or enter a UID to simulate a tap.

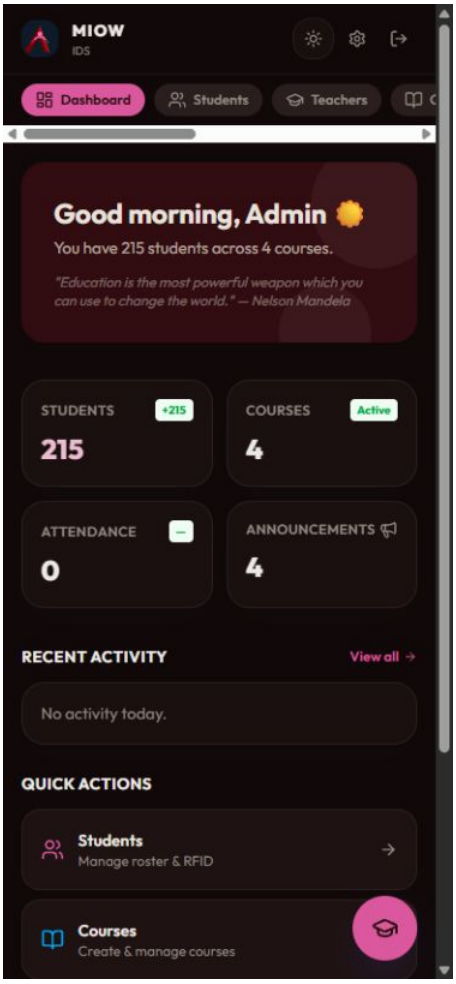

Fix: add persistent visible labels, a credential visibility control, and a clear recovery/contact path. Prefer PIN login on personal devices and reserve reader-first behavior for a clearly identified kiosk. Explain accepted credential formats consistently.

The supplied admin account accepted a four-digit PIN. Stronger administrator authentication deserves priority. The page states that five failed attempts cause a 15-minute lockout, but enforcement was not tested and no brute-force testing was performed.

7. Medium: mobile navigation hides key destinations

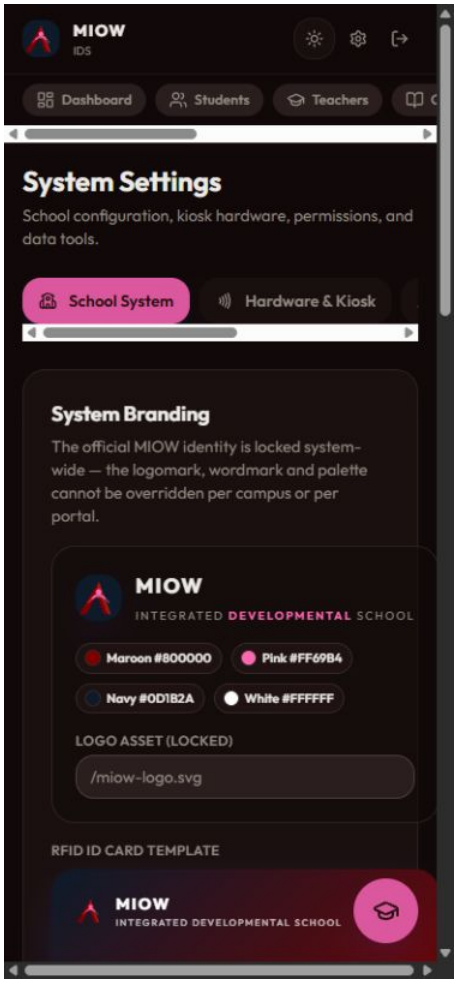

The mobile header displays a horizontally scrolling row of portal links. Only the first few destinations are immediately visible, and a conspicuous white native scrollbar interrupts the dark visual style. Settings adds a second horizontal row, increasing the need to discover sideways scrolling. The settings brand preview also presses against the right edge.

Evidence 05 - Mobile admin dashboard

Summary cards reflow; portal destinations require horizontal scrolling.

Evidence 09 - Mobile system settings

Two horizontal navigation rows and a brand preview crowded against the right edge.

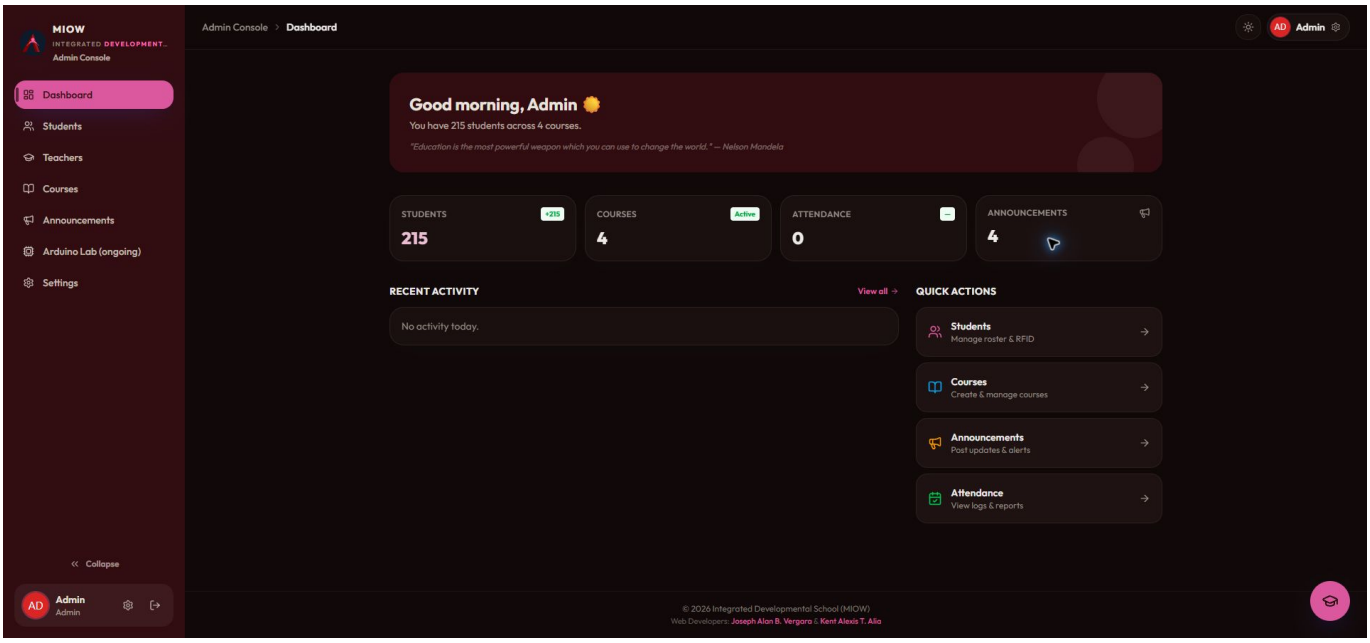

Fix: use a clearly labeled menu or drawer for the full portal navigation. Keep only the most useful destinations in a compact persistent navigation. Make overflow and scroll affordances deliberate, and constrain the settings preview to its container.

Evidence: Mobile dashboard (Evidence 05), Mobile settings (Evidence 09).

8. Lower priority: improve readable, actionable information

Secondary text, footer credits, helper text, and badges are small and visually muted. Desktop dashboard space is dominated by a greeting, a quotation, and an empty activity area; more useful information could include attendance exceptions, unassigned teachers, pending grading, and time-sensitive announcements. The Students badge **+215** also lacks a period explaining whether it represents growth or the total.

Evidence 04 - Desktop admin dashboard

Consistent cards and quick actions, with space available for more actionable information.

Login mode buttons are ordinary buttons with no **aria-selected**, **aria-pressed**, or tab role, so the active mode is not explicitly conveyed by their semantics. Add a proper selected state and keyboard behavior.

The settings screen displayed Academic Year **2025-2026**, while the login campaign advertised **2026-2027** enrollment. This is a displayed consistency concern; the underlying persisted configuration was not verified. Announcements use relative phrases such as Tomorrow and This Friday. Explicit event dates and expiry behavior would make them easier to trust after publication.

What works well

- Successful PIN login with Enter and successful sign-out.
- Consistent maroon/pink identity, rounded cards, and clear primary actions.
- Useful dashboard shortcuts and course grouping.
- Search and grade/section filters, with a helpful No matches state.
- Accessible names on login inputs, many icon actions, and destructive row actions.
- Dashboard skeletons and a mobile two-column summary layout.
- Course detail keeps worksheets, assignments, students, and schedule together.

Performance conclusion and remaining measurement

No warning/error entries were returned by the available Chrome console reader during the inspected flows. This does not establish that the network, server, or full application is error-free.

Navigation and search completed in this session, but automation duration includes browser-control overhead and is not an application latency benchmark. Performance remains **unmeasured**, with the large roster and misleading loading values identified as practical improvement targets.

To complete the requested quantitative performance audit, run Chrome DevTools Lighthouse in desktop and mobile profiles for **/auth**, the admin dashboard, and Students. Record a cold load and the filter/search interaction in the Performance panel; inspect the Network panel for avatar sizes, caching, duplicate requests, and failed responses. Collect at least three comparable runs and report the median alongside the device and throttling settings. Measure authenticated pages within the authenticated Chrome session.

Recommended order of work

1. Fix mobile login width and dialog focus containment.
2. Correct the admin attendance navigation and destination labeling.
3. Paginate the roster and improve avatar loading.
4. Replace temporary zero counts and blank route content with loading states.
5. Add login recovery, persistent labels, and selected mode semantics.
6. Improve mobile navigation, secondary text readability, and dashboard usefulness.
7. Complete the DevTools performance measurements before assigning a performance score.
